What are the best and worst things about having a father in UK Armed Forces? Analysis of free text responses

Vageesh Jain,¹ S A M Stevelink,² N T Fear²

ABSTRACT
Objective This study aims to explore what adolescents report as the best and worst aspects of having a father in the UK military.
Methods Qualitative data were collected from 171 adolescents aged 11–16 years, via an online questionnaire exploring the impact of paternal military service on childhood well-being (response rate=70%). Questions about the best and worst aspects of their father’s military role were examined. Content analysis has been used to code the qualitative data into themes.
Results 85 girls and 86 boys were included with a mean age of 13 years (SD 1.92). The results showed lack of contact as the single most commonly reported negative factor of having a father in the military (61%). Positive aspects of their fathers’ job most frequently reported included a sense of pride (25%) and financial benefits (25%).
Conclusions Adolescents take a great deal of pride in their father’s jobs in the military, and they enjoy the financial benefits. A majority, however, feel a lack of contact with their father is the most negative factor.

INTRODUCTION
The number of children who have a parent in the UK military is estimated to be just over 50 000.¹ The lifestyle of these children involves moving to new places as their mothers or fathers are given new assignments and recent reviews have found an increase in emotional and behavioural problems in children when a parent was deployed.²³ Deployment-related family stresses such as absence of their father’s for long periods, or fear of injury to their loved ones, are a commonly occurring part of their lives.⁴

The Royal Marines Children’s Fund recently undertook a project where several positive aspects of being part of the service community were identified.⁵ The findings suggested that children and young adults (below the age of 23 years) often take a great deal of pride, identity and belonging from their parent’s role in the UK Armed Forces. Service children often learn to be more adaptable, easily making friends and having a sense of perspective gained from living as a part of multiple communities.⁶

The current study aims to assess what adolescents report as the best and worst thing about having a father in the UK Armed Forces. Provision of an opportunity for the participants to express themselves via free text boxes, allowed a more indepth qualitative analysis than has been undertaken in the past.

METHODOLOGY
Participants
Fathers who were part of an already existing cohort founded by the King’s Centre for Military Health Research⁶ were selected for participation via a telephone interview. Following this the mothers of their children were invited to participate and complete an online questionnaire. Participating mothers were asked to provide consent for the research team to contact their children (aged 11–16 years) to invite them to participate in an online survey. From the 397 mothers that participated, consent was given to invite 249 of their children aged 11–16 years to participate in the study.

Data collection
Data collection began in July 2010 and ended in October 2012. If consent was provided, children were sent an information pack about the study, a consent form (for 16-year-olds) or an assent form (for those below 16 years). Data were collected using a self-report online questionnaire. The children’s questionnaire consisted of various questions including ‘what is the worst thing about having a father in the UK Armed Forces’ and ‘what is the best thing about having a father in the UK Armed Forces’, thereby allowing the children to give a free text response. The fathers’ online questionnaires provided data on the age and gender of their children.

Qualitative analysis
An inductive content analysis was used,⁷ targeted at the two questions: the ‘best thing’ and ‘worst thing’
about having a military father. Inductive content analysis depends on inductive reasoning, which has allowed themes to emerge from the raw data, through repeated examination and comparison. After familiarisation with the responses from the online questionnaire, themes were developed based on the most commonly occurring words. A coding scheme was developed via discussion between two of the authors (NF and VJ). This was originally trialled on a sample of 20 questionnaire responses, and then applied to the full sample of responses to the online questionnaire. Subsequently, all the responses were analysed individually and allocated to a particular theme. Responses that were similar or drew out the same concept were grouped together into one theme. This process was repeated three times. All authors agreed-upon the final coding scheme after revisions were made regarding the categorisation of some data. This scheme comprised 13 themes, of which eight themes were for the best thing about their father’s job in the UK Armed Forces, and five for the worst thing.

The qualitative data available varied by respondent, some responses were in full sentences and others just a few words and five (3%) respondents answered ‘I can’t remember’. There were 12 respondents who left ‘the worst thing about their father’s job’ blank, and five did the same for ‘the best thing’. Only those three who left both questions blank, or responded ‘don’t remember’ to both were completely excluded; eight responses (5%) contained more than one answer to the question (five responses for ‘best’ and three for ‘worst thing about having a military father’), and where this was the case the first answer was coded.

Ethics

The Ministry of Defence Research Ethics Committee and the King’s College Hospital NHS Research Ethics Committee provided ethical approval for this study.

RESULTS

A response was obtained from 176 children (a response rate of 70.7%); two children were excluded due to missing data leaving valid responses from 174 children (response rate=70%) (Figure 1). Overall, 88 girls and 86 boys were included with an age range of 11–16 years (mean 13; SD=1.92 years); 171 of these responses were taken forward for analysis due to incomplete data (n=3), leaving 85 girls and 86 boys.

Best thing about father being in the UK Armed Forces

The 166 free text responses for this question were grouped into themes (Table 1). Financial benefits, along with pride/respect for the job were the most common responses (25% each) with moving homes the next most popular response (21%). Some (12%) recalled the opportunity to learn new things as the best part of their father’s job; less common themes were being part of the military community (5%), father’s love for the job (4%) and feeling safe (1%). A small proportion stated that nothing was good about their father’s job (7%) (Table 1).

Worst thing about father being in the UK Armed Forces

The most noteworthy theme reported was lack of contact (61%) (Table 2), but 18% of the responses stated that there was nothing bad about their father’s job, with many claiming to be used to the long periods away. Although relocating was reported as one of the best things about their father’s job, a similar number of children saw it as a negative (16%). A few (3%) described the long-term impact of a life in the Armed Forces as the worst feature of a military career, and the same percentage were worried about their father’s safety on deployment (Table 2).

DISCUSSION

This study looked at how adolescents viewed the role of their father in the UK military using free text responses to a questionnaire. The key findings were that lack of contact was reported as the predominant factor negatively affecting children, while financial benefits and a sense of pride were most commonly reported as the positive benefits.

A RAND Corporation study conducted in 2009 found that children in military families face certain emotional challenges.
In particular, having a parent deployed for a long period of time was the most important factor associated with whether military children would struggle in their personal lives.9 This is consistent with our findings, as lack of contact was shown to be the most commonly reported negative aspect of having a military father.

Existing literature does indicate that children can be impacted in a positive way by their parents’ military roles. Service children continue to attain academic achievements surpassing the national standard.2 They often build strong bonds in their communities, shouldering extra responsibility while their serving parent is away.10 A recent paper explained that when children move around every few years with the army, it is possible for familiar faces to ‘often turn up in new places’.11 This is discussed as a positive aspect of forces life where, in schools with a majority of pupils from service families, children have similar experiences to share with each other. This beneficial feeling of being part of a close-knit military community was recalled as the best aspect of military life by a small fraction of participants in our current study (4%).

First, adolescents may have hesitated to write negative answers, as they feared for their father’s career. However, the information sheet sent out to everyone clearly stated the aims and objectives of the project and the research team being independent from the Ministry of Defence. Second, an age range of 11–16 years meant that we could not analyse responses of younger children, to see if they are impacted differently to adolescents, by their father’s jobs. Third, the questionnaire was completed online, making it impossible to ascertain whether children completed the survey by themselves or not. If those around the child influenced responses, this may have affected the validity of the results, but such a limitation is difficult to overcome when collecting data online. Finally, there were limitations relating to the application of the coding scheme, as this was done by one person.12 This makes the grouping of the data more prone to human error, decreasing its reliability.13 In order to reduce such inaccuracies the coding scheme was developed by collaboration with one of the other authors and then discussed with all authors and although applied by just one person, this was done three times on three separate occasions.

**Future directions**

Studies must explore the extent to which a child is affected by certain aspects of the military life by employing both qualitative and quantitative measures to assess exactly how much a child feels each factor of military life impacts their daily lives. A simple way to do this for instance would be to add a numerical severity scale on the questionnaire—where a high number on one of the negative aspects of military life meaning the child finds this factor so significant that it greatly impacts on their daily life in a detrimental way. A more indepth qualitative study should be attempted, perhaps with interviews, using the same approach as this one; to target the children and adolescents themselves, rather than the parents, in order to further understand their hardships and how best to try and address them.

**CONCLUSIONS**

Adolescents seem to report numerous things as the best thing about having a father in the UK Armed Forces, with no clear majority reporting one particular issue. However, a significant majority did report a lack of contact with their father as the most negative aspect of their father’s military role.

**Contributors** All authors were involved in the stage (planning, conduct and report) of the study. VJ is responsible for the overall content and the guarantor of this work.

**Funding** US Department of Defense.

**Competing interests** None declared.

**Ethics approval** King’s College Hospital NHS Research Ethics Committee and Ministry of Defense Research Ethics Committee.

**Provenance and peer review** Not commissioned; externally peer reviewed.
